In time series analysis, the Box-Jenkins method, named after the statisticians George Box and Gwilym Jenkins, applies autoregressive moving average (ARMA) or autoregressive integrated moving average (ARIMA) models to find the best fit of a time-series model to past values of a time series.

The book by Box and Jenkins, Time Series Analysis Forecasting and Control (the later edition is Box, Jenkins and Reinsel, 1994) has a discussion on these forecast functions on pages 326 - 328. Again, if you have only a faint notion, but you do know that there was a trend upwards before differencing, pick a seasonal MA term and see what comes out in the diagnostics.

The Box-Jenkins methodology is a five-step process for identifying, selecting, and assessing conditional mean models (for discrete, univariate time series data). Establish the stationarity of your time series. If your series is not stationary, successively difference your series to attain stationarity.

The first step in the Box-Jenkins procedure is to difference the time series until it is stationary, thereby ensuring that trend and seasonal components are removed. In many instances one or two stage differencing is sufficient. The differenced series will be shorter than the source series by c time steps, where c is the range of the differencing.
