Electrical defibrillation is the only effective therapy for cardiac arrest caused by ventricular fibrillation (VF) [1, 2] or pulseless ventricular tachycardia (VT).Scientific evidence to support early defibrillation is overwhelming [3-5], being delay from collapse to delivery of the first shock the single most important determinant of survival [6, 7].

Electrical defibrillation is the only practical means for halting ventricular fibrillation (VF). Although it has been known for more than a century that application of an electric shock directly to the myocardium causes VF, and that the heart can be returned to normal rhythm by subsequent application of a shock of greater magnitude, 1 - 3 knowledge of the mechanisms underlying the process of ...
